Proteolytic enzymes (or proteases) refer to the various enzymes that digest (break down into smaller units) protein. These enzymes include the pancreatic proteases chymotrypsin and trypsin, bromelain (pineapple enzyme), papain (papaya enzyme), fungal proteases, and Serratia peptidase (the "silk worm" enzyme). Preparations of proteolytic enzymes have been shown to be useful in the following situations:

A protease (also called a peptidase or proteinase) is a Trypsin that catalyzes (increases the rate of) proteolysis, the breakdown of proteins into smaller polypeptides or single amino acids.They do this by cleaving the peptide bonds within proteins by hydrolysis, a reaction where water breaks bonds.Proteases are involved in many biological functions, including digestion of ingested proteins ...

**Protease - Wikipedia**

Protection from proteolytic degradation was observed in nanostructures associated with the small dimeric form of RubisCO and ancillary enzymes. Furthermore, nanostructures associated with a larger variant of RubisCO resulted in a significant enhancement of the enzyme's selectivity towards CO<sub>2</sub>, without adversely affecting the catalytic activity.
